Metabolic therapy

- The main principles for determining metabolic disorders: diagnostics, blood and urine tests to assess the health status and determine the level of hormones.
- "Body monitoring" - analysis of body composition allows you to estimate the percentage ratio of adipose tissue, bone tissue and water in the body, calculate the metabolic age.
- iPRO - 3-day glycemic monitoring - continuous and automatic determination of blood sugar levels by an established subcutaneous sensor, usually for 3 days.
- This definition of blood sugar fluctuations gives a complete information of the hidden and high concentrations of glucose, which cannot be detected when measuring with a blood glucose meter. The method allows the doctor and patient to assess changes in blood sugar levels during the day. This method is used to identify violations of sugar levels, assess the degree of compensation and the correctness of diabetes treatment.
